

Coevolution between iAnts and Obstacles

Troy Squillaci

Project Inspiration

Obstacles in Complex Systems

Can obstacles be evolved to inhibit the foraging capabilities of iAnts?

Simulation Parameters

- Simulation
 - 256 Randomly Distributed Food Tags
 - 30min Simulation Time
 - 40 Population Size, 20 Generations
 - Truncation Selection (Elite Size 8), One-Point Crossover, Gaussian Mutation
- iAnts
 - Six Agents
 - Standard CPFA Parameters Evolved
- Obstacles
 - Four Agents
 - Fixed Size (2, 0.1, 0.5)
 - Orientation and Position Evolved
 - Nest Obstruction Prevented

GA Features

- Uniform-Normal Population Initialization for Diversity
- Dynamic Code Injection
 - Alter functions at runtime (selection, crossover, mutation, etc...)
 - Change which function is used at runtime (example: truncation to tournament selection)
- Multi-processing
 - Divide and conquer ARGoS simulations, utilizing all processing cores.
- JSON configuration for describing the GA and agents, minimal code fiddling needed to completely change GA functionality.
- Extensive logging.

(iAnts) Elite Fitness Values

(Obstacles) Elite Fitness Values

(Obstacles) Elite Mean

Example of Elite Obstacle Configuration (Gen 20)

Video of Obstructed iAnts

Current Issues

- Fitness Function
 - Obstacle Fitness = $1 - \text{iAnt Fitness}$
 - Obstacles initially outperform iAnts, is this beneficial or detrimental?
- Other
 - Currently, portions of obstacles can be out of bounds of the arena.
 - ARGoS occasionally enters an infinite loop, ruining the entire GA run. Ideas?

Future Plans

- Stationary Food Clusters (Constant Seed, Cluster Distribution)
- Tilting Obstacles (could result in the formation of ramps and pits)
- Attempt to implement novelty search for either or both sets of agents.
